1 Introduction

Given the opportunity to review the design document and related source code of the `Dypius` protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About Dypius

`Dypius` is a powerful, decentralized ecosystem with a focus on scalability, security, and global adoption through next-generation infrastructure. It offers a variety of products and services that cater to both beginners and advanced users in the crypto space including `DeFi` solutions, analytical tools, `NFTs`, and `Metaverse`. The basic information of the audited protocol is as follows:

Table 1.1: Basic Information of The Dypius

Item	Description
Name	Dypius
Type	EVM Smart Contract
Platform	Solidity
Audit Method	Whitebox
Latest Audit Report	October 22, 2023

In the following, we show the Git repository of reviewed files and the commit hash value used in this audit. Note this audit covers the following three contracts: `dypius.sol`, `bridge_dyp_mint.sol`, and `Bridge.sol`.

1.2 About PeckShield

PeckShield Inc. [8] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

Impact \ Likelihood	*High*	*Medium*	*Low*
High	Critical	High	Medium
Medium	High	Medium	Low
Low	Medium	Low	Low

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [6]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the

Table 1.3: The Full List of Check Items

Category	Check Item
Basic Coding Bugs	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function
	Overflows & Underflows
	Reentrancy
	Money-Giving Bug
	Blackhole
	Unauthorized Self-Destruct
	Revert DoS

	Kill-Switch Mechanism
	Operation Trails & Event Generation
	ERC20 Idiosyncrasies Handling
	Frontend-Contract Integration
	Deployment Consistency
	Holistic Risk Management
Additional Recommendations	Avoiding Use of Variadic Byte Array
	Using Fixed Compiler Version
	Making Visibility Level Explicit
	Making Type Inference Explicit
	Adhering To Function Declaration Strictly
	Following Other Best Practices

contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [5], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the `Dypius` protocol. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	1	■
Low	1	■
Informational	0	
Total	2	

We have so far identified a list of potential issues. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 1 low-severity vulnerability.

Table 2.1: Key Dypius Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Voting Amplification With Sybil Attacks	Business Logic	Resolved
PVE-002	Medium	Trust Issue of Admin Keys	Security Features	Resolved

Besides recommending specific countermeasures to mitigate these issues, we also emphasize that it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms need to kick in at the very moment when the contracts are being deployed in mainnet. Please refer to Section 3 for details.

3 | Detailed Results

3.1 Voting Amplification With Sybil Attacks

- ID: PVE-001
- Severity: Low
- Likelihood: High
- Impact: Low
- Target: Dypius
- Category: Business Logic [4]
- CWE subcategory: CWE-841 [2]

Description

In Dypius, the protocol token DYP is enhanced with voting support so that it can be used to cast and record the votes. Moreover, the DYP contract allows for dynamic delegation of a voter to another, though the delegation is not transitive. When a submitted proposal is being tallied, the number of votes can be counted prior to the proposal's proposal.startBlock.

Our analysis on the DYP shows that the its voting use may be vulnerable to a so-called Sybil attack [7]. For elaboration, let's assume at the very beginning there is a malicious actor named Malice, who owns 100 DYP tokens. Malice has an accomplice named Trudy who currently has 0 balance of DYP. This Sybil attack can be launched as follows:

```
    function _delegate(address delegator, address delegatee)
        internal
    {
        address currentDelegate = _delegates[delegator];
        uint256 delegatorBalance = balanceOf(delegator); // balance of underlying DYPs (
            not scaled);
        _delegates[delegator] = delegatee;

        emit DelegateChanged(delegator, currentDelegate, delegatee);

        _moveDelegates(currentDelegate, delegatee, delegatorBalance);
    }

    function _moveDelegates(address srcRep, address dstRep, uint256 amount) internal {
        if (srcRep != dstRep && amount > 0) {
```

```
            if (srcRep != address(0)) {
                // decrease old representative
                uint32 srcRepNum = numCheckpoints[srcRep];
                uint256 srcRepOld = srcRepNum > 0 ? checkpoints[srcRep][srcRepNum - 1].
                    votes : 0;
                uint256 srcRepNew = srcRepOld.sub(amount);
                _writeCheckpoint(srcRep, srcRepNum, srcRepOld, srcRepNew);
            }

            if (dstRep != address(0)) {
                // increase new representative
                uint32 dstRepNum = numCheckpoints[dstRep];
                uint256 dstRepOld = dstRepNum > 0 ? checkpoints[dstRep][dstRepNum - 1].
                    votes : 0;
                uint256 dstRepNew = dstRepOld.add(amount);
                _writeCheckpoint(dstRep, dstRepNum, dstRepOld, dstRepNew);
            }
        }
    }
```

Listing 3.1: Dypius::_delegate()

1. `Malice` initially delegates the voting to `Trudy`. Right after the initial delegation, `Trudy` can have 100 votes if he chooses to cast the vote.

2. `Malice` transfers the full 100 balance to M_1 who also delegates the voting to `Trudy`. Right after this delegation, `Trudy` can have 200 votes if he chooses to cast the vote. The reason is that the `DYP` contract's `transfer()` does NOT `_moveDelegates()` together. In other words, even now `Malice` has 0 balance, the initial delegation (of `Malice`) to `Trudy` will not be affected, therefore `Trudy` still retains the voting power of 100 `DYPs`. When M_1 delegates to `Trudy`, since M_1 now has 100 `DYPs`, `Trudy` will get additional 100 votes, totaling 200 votes.

3. We can repeat by transferring M_i's 100 `DYPs` balance to M_{i+1} who also delegates the votes to `Trudy`. Every iteration will essentially add 100 voting power to `Trudy`. In other words, we can effectively amplify the voting powers of `Trudy` arbitrarily with new accounts created and iterated!

Recommendation To mitigate, it is necessary to accompany every single `transfer()` and `transferFrom()` with the `_moveDelegates()` so that the voting power of the sender's delegate will be moved to the destination's delegate. By doing so, we can effectively mitigate the above `Sybil` attacks.

Status This issue has been resolved as the team confirms this feature is deprecated and will not be used.

3.2 Trust Issue of Admin Keys

- ID: PVE-002
- Severity: Medium
- Likelihood: Low
- Impact: High
- Target: Bridge
- Category: Security Features [3]
- CWE subcategory: CWE-287 [1]

Description

In Dypius, there is a privileged administrative account, i.e., owner. The administrative account plays a critical role in governing and regulating the protocol-wide operations. Our analysis shows that this privileged account needs to be scrutinized. In the following, we use the Bridge contract as an example and show the representative functions potentially affected by the privileges of the administrative account.

```
function transferOwnershipDyp(address newOwner) external onlyOwner {
    require(newOwner != address(0), "Ownable: new owner is the zero address");
    dypContract.transferOwnership(newOwner);

    emit TransferOwnershipDyp(newOwner);
}

function setVerifyAddress(address newVerifyAddress) external noContractsAllowed
    onlyOwner {
    verifyAddress = newVerifyAddress;
}
function setDailyLimit(uint newDailyTokenWithdrawLimitPerAccount) external
    noContractsAllowed onlyOwner {
    dailyTokenWithdrawLimitPerAccount = newDailyTokenWithdrawLimitPerAccount;
}
```

Listing 3.2: Example Privileged Operations in Bridge

We understand the need of the privileged functions for contract maintenance, but at the same time the extra power to the administrative account may also be a counter-party risk to the protocol users. It would be worrisome if the privileged administrative account is a plain EOA account. Note that a multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed DAO.

Recommendation Promptly transfer the privileged account to the intended DAO-like governance contract. All changes to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been resolved as the following admin functions have been removed, including `transferAnyERC20Token()` and `transferOwnershipDyp()`.

4 Conclusion

In this audit, we have analyzed the design and implementation of the `Dypius` protocol, which is a powerful, decentralized ecosystem with a focus on scalability, security, and global adoption through next-generation infrastructure. It offers a variety of products and services that cater to both beginners and advanced users in the crypto space including `DeFi` solutions, analytical tools, `NFTs`, and `Metaverse`. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Meanwhile, we need to emphasize that `Solidity`-based smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
